

Month of birth linked to natal and adult differences, study suggests

An adult's behaviour, morphology and physiology develops throughout its life, and their development depends on the interaction between the genes it has and the environment in which it grows. Pre-natal conditions can have long-lasting effects on all of these traits, even beyond the age of sexual maturity. Recently, researchers from the University of Cambridge (UK) have found links between the month when a baby is born and several post-natal traits.
